# **Artificial Intelligence Nanodegree**

## **Convolutional Neural Networks**

# Project: Write an Algorithm for a Dog Identification App

In this notebook, some template code has already been provided for you, and you will need to implement additional functionality to successfully complete this project. You will not need to modify the included code beyond what is requested. Sections that begin with '(IMPLEMENTATION)' in the header indicate that the following block of code will require additional functionality which you must provide. Instructions will be provided for each section, and the specifics of the implementation are marked in the code block with a 'TODO' statement. Please be sure to read the instructions carefully!

**Note**: Once you have completed all of the code implementations, you need to finalize your work by exporting the iPython Notebook as an HTML document. Before exporting the notebook to html, all of the code cells need to have been run so that reviewers can see the final implementation and output. You can then export the notebook by using the menu above and navigating to \n", "**File -> Download as -> HTML (.html)**. Include the finished document along with this notebook as your submission.

In addition to implementing code, there will be questions that you must answer which relate to the project and your implementation. Each section where you will answer a question is preceded by a 'Question X' header. Carefully read each question and provide thorough answers in the following text boxes that begin with 'Answer:'. Your project submission will be evaluated based on your answers to each of the questions and the implementation you provide.

**Note:** Code and Markdown cells can be executed using the **Shift + Enter** keyboard shortcut. Markdown cells can be edited by double-clicking the cell to enter edit mode.

The rubric contains *optional* "Stand Out Suggestions" for enhancing the project beyond the minimum requirements. If you decide to pursue the "Stand Out Suggestions", you should include the code in this IPython notebook.

# Why We're Here

In this notebook, you will make the first steps towards developing an algorithm that could be used as part of a mobile or web app. At the end of this project, your code will accept any user-supplied image as input. If a dog is detected in the image, it will provide an estimate of the dog's breed. If a human is detected, it will provide an estimate of the dog breed that is most resembling. The image below displays potential sample output of your finished project (... but we expect that each student's algorithm will behave differently!).

In this real-world setting, you will need to piece together a series of models to perform different tasks; for instance, the algorithm that detects humans in an image will be different from the CNN that infers dog breed. There are many points of possible failure, and no perfect algorithm exists. Your imperfect solution will nonetheless create a fun user experience!

## The Road Ahead

We break the notebook into separate steps. Feel free to use the links below to navigate the notebook.

- Step 0: Import Datasets
- Step 1: Detect Humans
- Step 2: Detect Dogs
- Step 3: Create a CNN to Classify Dog Breeds (from Scratch)
- Step 4: Use a CNN to Classify Dog Breeds (using Transfer Learning)
- Step 5: Create a CNN to Classify Dog Breeds (using Transfer Learning)
- Step 6: Write your Algorithm
- Step 7: Test Your Algorithm

# **Step 0: Import Datasets**

# **Import Dog Dataset**

In the code cell below, we import a dataset of dog images. We populate a few variables through the use of the load files function from the scikit-learn library:

- train files, valid files, test files numpy arrays containing file paths to images
- train\_targets, valid\_targets, test\_targets numpy arrays containing onehot-encoded classification labels

```
In [2]: from sklearn.datasets import load files
        from keras.utils import np utils
        import numpy as np
        from glob import glob
        # define function to load train, test, and validation datasets
        def load dataset(path):
            data = load files(path)
            dog_files = np.array(data['filenames'])
            dog_targets = np_utils.to_categorical(np.array(data['target']), 133)
            return dog_files, dog_targets
        # load train, test, and validation datasets
        train files, train targets = load dataset('dogImages/train')
        valid_files, valid_targets = load_dataset('dogImages/valid')
        test_files, test_targets = load_dataset('dogImages/test')
        # load list of dog names
        dog_names = [item[20:-1] for item in sorted(glob("dogImages/train/*/"))]
        # print statistics about the dataset
        print('There are %d total dog categories.' % len(dog_names))
        print('There are %s total dog images.\n' % len(np.hstack([train_files, v
        alid_files, test_files])))
        print('There are %d training dog images.' % len(train files))
        print('There are %d validation dog images.' % len(valid_files))
        print('There are %d test dog images.'% len(test files))
        Using TensorFlow backend.
```

```
There are 133 total dog categories. There are 8351 total dog images.

There are 6680 training dog images. There are 835 validation dog images. There are 836 test dog images.
```

# **Import Human Dataset**

In the code cell below, we import a dataset of human images, where the file paths are stored in the numpy array human files.

```
In [3]: import random
    random.seed(8675309)

# load filenames in shuffled human dataset
    human_files = np.array(glob("lfw/*/*"))
    random.shuffle(human_files)

# print statistics about the dataset
    print('There are %d total human images.' % len(human_files))
```

There are 13233 total human images.

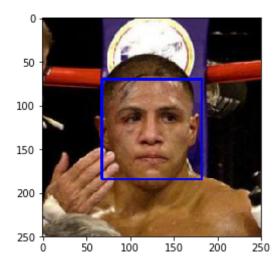

# **Step 1: Detect Humans**

We use OpenCV's implementation of <u>Haar feature-based cascade classifiers</u> (<a href="http://docs.opencv.org/trunk/d7/d8b/tutorial\_py\_face\_detection.html">http://docs.opencv.org/trunk/d7/d8b/tutorial\_py\_face\_detection.html</a>) to detect human faces in images. OpenCV provides many pre-trained face detectors, stored as XML files on <a href="https://github.com/opencv/opencv/tree/master/data/haarcascades">https://github.com/opencv/opencv/tree/master/data/haarcascades</a>). We have downloaded one of these detectors and stored it in the <a href="haarcascades">haarcascades</a> directory.

In the next code cell, we demonstrate how to use this detector to find human faces in a sample image.

# In [4]: import cv2 import matplotlib.pyplot as plt %matplotlib inline # extract pre-trained face detector face\_cascade = cv2.CascadeClassifier('haarcascades/haarcascade\_frontalfa ce\_alt.xml') # load color (BGR) image img = cv2.imread(human\_files[3]) # convert BGR image to grayscale gray = cv2.cvtColor(img, cv2.COLOR\_BGR2GRAY) # find faces in image faces = face\_cascade.detectMultiScale(gray) # print number of faces detected in the image print('Number of faces detected:', len(faces)) # get bounding box for each detected face for (x,y,w,h) in faces: # add bounding box to color image cv2.rectangle(img,(x,y),(x+w,y+h),(255,0,0),2)# convert BGR image to RGB for plotting cv\_rgb = cv2.cvtColor(img, cv2.COLOR\_BGR2RGB) # display the image, along with bounding box plt.imshow(cv rgb) plt.show()

Number of faces detected: 1

Before using any of the face detectors, it is standard procedure to convert the images to grayscale. The detectMultiScale function executes the classifier stored in face\_cascade and takes the grayscale image as a parameter.

In the above code, faces is a numpy array of detected faces, where each row corresponds to a detected face. Each detected face is a 1D array with four entries that specifies the bounding box of the detected face. The first two entries in the array (extracted in the above code as x and y) specify the horizontal and vertical positions of the top left corner of the bounding box. The last two entries in the array (extracted here as w and h) specify the width and height of the box.

## Write a Human Face Detector

We can use this procedure to write a function that returns True if a human face is detected in an image and False otherwise. This function, aptly named face\_detector, takes a string-valued file path to an image as input and appears in the code block below.

```
In [5]: # returns "True" if face is detected in image stored at img_path
    def face_detector(img_path):
        img = cv2.imread(img_path)
        gray = cv2.cvtColor(img, cv2.COLOR_BGR2GRAY)
        faces = face_cascade.detectMultiScale(gray)
        return len(faces) > 0
```

# (IMPLEMENTATION) Assess the Human Face Detector

Question 1: Use the code cell below to test the performance of the face detector function.

- What percentage of the first 100 images in human files have a detected human face?
- What percentage of the first 100 images in dog files have a detected human face?

Ideally, we would like 100% of human images with a detected face and 0% of dog images with a detected face. You will see that our algorithm falls short of this goal, but still gives acceptable performance. We extract the file paths for the first 100 images from each of the datasets and store them in the numpy arrays human\_files\_short and dog\_files\_short.

## **Answer:**

98% of the first 100 images in human files have a detected human face

11% of the first 100 images in dog files have a detected human face

```
In [6]: human_files_short = human_files[:100]
        dog files short = train files[:100]
        # Do NOT modify the code above this line.
        ## TODO: Test the performance of the face detector algorithm
        ## on the images in human_files_short and dog_files_short.
        human counter = 0
        dog_counter = 0
        face_detected = 0
        for human in human_files_short:
            face_detected = 1 if face_detector(human) else 0
            human_counter += face_detected
        print('Number of faces detected in human files:', human_counter)
        print('percentage of human faces detected in dog files', human_counter/(
        len(human_files_short)))
        for dog in dog_files_short:
            face detected = 1 if face detector(dog) else 0
            dog_counter += face_detected
        print('Number of faces detected in dog files:', dog_counter)
        print('percentage of human faces detected in dog files', dog_counter/(le
        n(dog_files_short)))
```

Number of faces detected in human files: 98 percentage of human faces detected in dog files 0.98 Number of faces detected in dog files: 11 percentage of human faces detected in dog files 0.11

**Question 2:** This algorithmic choice necessitates that we communicate to the user that we accept human images only when they provide a clear view of a face (otherwise, we risk having unneccessarily frustrated users!). In your opinion, is this a reasonable expectation to pose on the user? If not, can you think of a way to detect humans in images that does not necessitate an image with a clearly presented face?

### **Answer:**

This is a reasonable expectation to pose on the user, though not ideal. Machine learning at current stage can do a lot more advanced face detection, including detecting faces presented from different angels, in different lighting, with various degrees of distortion etc. Google and Facebook, among others, are also able to do accurate face-recognition.

Different algorithms have been developed to detect human faces in different conditions. One of them is called face landmark estimation. It basically maps out a human face into 68 points / landmarks, the shape of the face, positions and contours of eyes, nose, mouth, etc. When the map is constructed, the image can be scaled, rotated and transformed images to obtain a roughly front and center face view.

<u>OpenFace (https://cmusatyalab.github.io/openface/)</u> has a very popular library and is doing a great job detecting faces and recognize public figures (such as Barack Obama and Will Farrell). I have not able to install the openface library to try it out.

## Reference(s):

Machine Learning is Fun! Part 4: Modern Face Recognition with Deep Learning (https://medium.com/@ageitgey/machine-learning-is-fun-part-4-modern-face-recognition-with-deep-learning-c3cffc121d78)

We suggest the face detector from OpenCV as a potential way to detect human images in your algorithm, but you are free to explore other approaches, especially approaches that make use of deep learning:). Please use the code cell below to design and test your own face detection algorithm. If you decide to pursue this *optional* task, report performance on each of the datasets.

```
In [19]: ## (Optional) TODO: Report the performance of another
## face detection algorithm on the LFW dataset
### Feel free to use as many code cells as needed.
```

# **Step 2: Detect Dogs**

In this section, we use a pre-trained ResNet-50

(http://ethereon.github.io/netscope/#/gist/db945b393d40bfa26006) model to detect dogs in images. Our first line of code downloads the ResNet-50 model, along with weights that have been trained on <a href="mageNet">ImageNet</a> (http://www.image-net.org/), a very large, very popular dataset used for image classification and other vision tasks. ImageNet contains over 10 million URLs, each linking to an image containing an object from one of <a href="mage1000">1000</a> categories (https://gist.github.com/yrevar/942d3a0ac09ec9e5eb3a). Given an image, this pre-trained ResNet-50 model returns a prediction (derived from the available categories in ImageNet) for the object that is contained in the image.

```
In [7]: from keras.applications.resnet50 import ResNet50
# define ResNet50 model
ResNet50_model = ResNet50(weights='imagenet')
```

## **Pre-process the Data**

When using TensorFlow as backend, Keras CNNs require a 4D array (which we'll also refer to as a 4D tensor) as input, with shape

```
(nb_samples, rows, columns, channels),
```

where nb\_samples corresponds to the total number of images (or samples), and rows, columns, and channels correspond to the number of rows, columns, and channels for each image, respectively.

The path\_to\_tensor function below takes a string-valued file path to a color image as input and returns a 4D tensor suitable for supplying to a Keras CNN. The function first loads the image and resizes it to a square image that is  $224 \times 224$  pixels. Next, the image is converted to an array, which is then resized to a 4D tensor. In this case, since we are working with color images, each image has three channels. Likewise, since we are processing a single image (or sample), the returned tensor will always have shape

The paths\_to\_tensor function takes a numpy array of string-valued image paths as input and returns a 4D tensor with shape

```
(nb samples, 224, 224, 3).
```

Here, nb\_samples is the number of samples, or number of images, in the supplied array of image paths. It is best to think of nb\_samples as the number of 3D tensors (where each 3D tensor corresponds to a different image) in your dataset!

```
In [8]: from keras.preprocessing import image
    from tqdm import tqdm

def path_to_tensor(img_path):
        # loads RGB image as PIL.Image.Image type
        img = image.load_img(img_path, target_size=(224, 224))
        # convert PIL.Image.Image type to 3D tensor with shape (224, 224, 3)
        x = image.img_to_array(img)
        # convert 3D tensor to 4D tensor with shape (1, 224, 224, 3) and ret
    urn 4D tensor
        return np.expand_dims(x, axis=0)

def paths_to_tensor(img_paths):
        list_of_tensors = [path_to_tensor(img_path) for img_path in tqdm(img_paths)]
        return np.vstack(list_of_tensors)
```

## **Making Predictions with ResNet-50**

Getting the 4D tensor ready for ResNet-50, and for any other pre-trained model in Keras, requires some additional processing. First, the RGB image is converted to BGR by reordering the channels. All pre-trained models have the additional normalization step that the mean pixel (expressed in RGB as [103.939, 116.779, 123.68] and calculated from all pixels in all images in ImageNet) must be subtracted from every pixel in each image. This is implemented in the imported function preprocess\_input. If you're curious, you can check the code for preprocess\_input here (https://github.com/fchollet/keras/blob/master/keras/applications/imagenet\_utils.py).

Now that we have a way to format our image for supplying to ResNet-50, we are now ready to use the model to extract the predictions. This is accomplished with the predict method, which returns an array whose i-th entry is the model's predicted probability that the image belongs to the i-th ImageNet category. This is implemented in the ResNet50\_predict\_labels function below.

By taking the argmax of the predicted probability vector, we obtain an integer corresponding to the model's predicted object class, which we can identify with an object category through the use of this <u>dictionary</u> (<a href="https://gist.github.com/yrevar/942d3a0ac09ec9e5eb3a">https://gist.github.com/yrevar/942d3a0ac09ec9e5eb3a</a>).

```
In [9]: from keras.applications.resnet50 import preprocess_input, decode_predict
ions

def ResNet50_predict_labels(img_path):
    # returns prediction vector for image located at img_path
    img = preprocess_input(path_to_tensor(img_path))
    return np.argmax(ResNet50_model.predict(img))
```

## Write a Dog Detector

While looking at the <u>dictionary (https://gist.github.com/yrevar/942d3a0ac09ec9e5eb3a)</u>, you will notice that the categories corresponding to dogs appear in an uninterrupted sequence and correspond to dictionary keys 151-268, inclusive, to include all categories from 'Chihuahua' to 'Mexican hairless'. Thus, in order to check to see if an image is predicted to contain a dog by the pre-trained ResNet-50 model, we need only check if the ResNet50\_predict\_labels function above returns a value between 151 and 268 (inclusive).

We use these ideas to complete the dog\_detector function below, which returns True if a dog is detected in an image (and False if not).

```
In [10]: ### returns "True" if a dog is detected in the image stored at img_path
    def dog_detector(img_path):
        prediction = ResNet50_predict_labels(img_path)
        return ((prediction <= 268) & (prediction >= 151))
```

## (IMPLEMENTATION) Assess the Dog Detector

**Question 3:** Use the code cell below to test the performance of your dog\_detector function.

- What percentage of the images in human\_files\_short have a detected dog?
- What percentage of the images in dog files short have a detected dog?

## **Answer:**

2% of of the images in <code>human\_files\_short</code> have a detected dog

100% of the images in dog files short have a detected dog

```
In [11]: ### TODO: Test the performance of the dog detector function
         ### on the images in human files short and dog files short.
         human counter = 0
         dog_counter = 0
         face detected = 0
         for human in human_files_short:
             face detected = 1 if dog detector(human) else 0
             human_counter += face_detected
         print('Number of dog faces detected in human files:', human_counter)
         print('percentage of dog faces detected in human files', human_counter/(
         len(human_files_short)))
         for dog in dog_files_short:
             face_detected = 1 if dog_detector(dog) else 0
             dog_counter += face_detected
         print('Number of dog faces detected in dog files:', dog_counter)
         print('percentage of dog faces detected in dog files', dog counter/(len(
         dog_files_short)))
```

Number of dog faces detected in human files: 2 percentage of dog faces detected in human files 0.02 Number of dog faces detected in dog files: 100 percentage of dog faces detected in dog files 1.0

# Step 3: Create a CNN to Classify Dog Breeds (from Scratch)

Now that we have functions for detecting humans and dogs in images, we need a way to predict breed from images. In this step, you will create a CNN that classifies dog breeds. You must create your CNN *from scratch* (so, you can't use transfer learning *yet*!), and you must attain a test accuracy of at least 1%. In Step 5 of this notebook, you will have the opportunity to use transfer learning to create a CNN that attains greatly improved accuracy.

Be careful with adding too many trainable layers! More parameters means longer training, which means you are more likely to need a GPU to accelerate the training process. Thankfully, Keras provides a handy estimate of the time that each epoch is likely to take; you can extrapolate this estimate to figure out how long it will take for your algorithm to train.

We mention that the task of assigning breed to dogs from images is considered exceptionally challenging. To see why, consider that *even a human* would have great difficulty in distinguishing between a Brittany and a Welsh Springer Spaniel.

Brittany	Welsh Springer Spaniel	

It is not difficult to find other dog breed pairs with minimal inter-class variation (for instance, Curly-Coated Retrievers and American Water Spaniels).

Curly-Coated Retriever	American Water Spaniel	

Likewise, recall that labradors come in yellow, chocolate, and black. Your vision-based algorithm will have to conquer this high intra-class variation to determine how to classify all of these different shades as the same breed.

Yellow Labrador Chocolate Labrador		Black Labrador	

We also mention that random chance presents an exceptionally low bar: setting aside the fact that the classes are slightly imabalanced, a random guess will provide a correct answer roughly 1 in 133 times, which corresponds to an accuracy of less than 1%.

Remember that the practice is far ahead of the theory in deep learning. Experiment with many different architectures, and trust your intuition. And, of course, have fun!

# **Pre-process the Data**

We rescale the images by dividing every pixel in every image by 255.

# In [12]: from PIL import ImageFile ImageFile.LOAD\_TRUNCATED\_IMAGES = True # pre-process the data for Keras train\_tensors = paths\_to\_tensor(train\_files).astype('float32')/255 valid\_tensors = paths\_to\_tensor(valid\_files).astype('float32')/255 test\_tensors = paths\_to\_tensor(test\_files).astype('float32')/255

```
100% | 6680/6680 [00:53<00:00, 124.97it/s]
100% | 835/835 [00:06<00:00, 138.90it/s]
100% | 836/836 [00:05<00:00, 139.80it/s]
```

# (IMPLEMENTATION) Model Architecture

Create a CNN to classify dog breed. At the end of your code cell block, summarize the layers of your model by executing the line:

model.summary()

We have imported some Python modules to get you started, but feel free to import as many modules as you need. If you end up getting stuck, here's a hint that specifies a model that trains relatively fast on CPU and attains >1% test accuracy in 5 epochs:

**Question 4:** Outline the steps you took to get to your final CNN architecture and your reasoning at each step. If you chose to use the hinted architecture above, describe why you think that CNN architecture should work well for the image classification task.

## **Answer:**

I followed one of the most common form of a ConvNet architecture, in which a layer stack is built with one or two Conv layers with ReLU activation, then a MaxPooling layer, then the pattern repeats (more Conv layers then a MaxPooling layer), until the image is abstracted spatially into a small size. Then I connect it to fully connected / dense layer using RELU as activation layer. After which, a full connected layer with softmax activation outputs the final result.

I also added Dropout layers to battle overfitting issues.

Detailed architecture reasoning and construction is as the following:

## Stack #1:

- 1. Convolutional layer #1: Applies 16 3x3 filters, with ReLU activation function and padding as 'Same', which specify that the output tensor should have the same width and height as the input tensor. The output tensor produced by this layer has a shape of [batch\_size, 224, 224, 16]. It has the same width and height as the input layer, however it has 16 channel.
- 2. Pooling Layer #1: Performs max pooling with a 2x2 filter. The output tensor produced by this layer has a shape of [batch\_size, 112, 16]; the 2x2 filter reduces width and height of the previous feature map by half.

## Stack #2:

- 1. Convolutional layer #2: 32 filters of 3 \* 3 regions, same padding, ReLU activation. This is by the common pattern which with every additional stack, the channel of depth generally doubles from the previous stack.
- 2. Convolutional layer #3: 32 filters of 3 \* 3 regions, same padding, ReLU activation
- 3. Dropout layer #1: dropout layer with regularization rate of 0.25. By doing so, 25% of of the elements will be randomly dropped out.
- 4. Pooling Layer #2: Performs max pooling with a 2x2 filter. The output tensor produced by this layer has a shape of [batch\_size, 56, 56, 32].

## Stack #3:

- 1. Convolutional Layer #5: 64 filters of 3 \* 3 regions, same padding, ReLU activation
- 2. Convolutional Layer #6: 64 filters of 3 \* 3 regions, same padding, ReLU activation
- 3. Pooling Layer #3: here a gloabal average pooling layer is used to output the spatial averages of the tensors

Full connected layers to prepare the final predictions:

- 1. Dense Layer #1: , a fully connected layer of 1,024 neurons to connect with the output tensor from the preceding layer, with dropout regularization rate set at 0.4.
- 2. Dropout layer #2: The final layer is the results layer. It is a fully connected dense layer with softmax activations and 133 neurons, one for each of the dog categories.

# **Compile the Model**

```
In [95]: import keras
    opt = keras.optimizers.rmsprop(lr=0.001)
    model.compile(optimizer=opt, loss='categorical_crossentropy', metrics=[
    'accuracy'])
```

# (IMPLEMENTATION) Train the Model

Train your model in the code cell below. Use model checkpointing to save the model that attains the best validation loss.

You are welcome to <u>augment the training data (https://blog.keras.io/building-powerful-image-classification-models-using-very-little-data.html)</u>, but this is not a requirement.

```
Train on 6680 samples, validate on 835 samples

## **Load the Model with the Best Validation Loss**

```
In [97]: model.load_weights('saved_models/weights.best.from_scratch.hdf5')
```

## Test the Model

Try out your model on the test dataset of dog images. Ensure that your test accuracy is greater than 1%.

```
In [99]: bottleneck_features = np.load('bottleneck_features/DogVGG16Data.npz')
    train_VGG16 = bottleneck_features['train']
    valid_VGG16 = bottleneck_features['valid']
    test_VGG16 = bottleneck_features['test']
```

## **Model Architecture**

The model uses the the pre-trained VGG-16 model as a fixed feature extractor, where the last convolutional output of VGG-16 is fed as input to our model. We only add a global average pooling layer and a fully connected layer, where the latter contains one node for each dog category and is equipped with a softmax.

```
In [100]: VGG16_model = Sequential()
    VGG16_model.add(GlobalAveragePooling2D(input_shape=train_VGG16.shape[1
    :]))
    VGG16_model.add(Dense(133, activation='softmax'))
    VGG16_model.summary()
```

## Load the Model with the Best Validation Loss

```
In [103]: VGG16_model.load_weights('saved_models/weights.best.VGG16.hdf5')
```

## **Test the Model**

Now, we can use the CNN to test how well it identifies breed within our test dataset of dog images. We print the test accuracy below.

```
In [104]: # get index of predicted dog breed for each image in test set
    VGG16_predictions = [np.argmax(VGG16_model.predict(np.expand_dims(featur
    e, axis=0))) for feature in test_VGG16]

# report test accuracy
    test_accuracy = 100*np.sum(np.array(VGG16_predictions)==np.argmax(test_t
        argets, axis=1))/len(VGG16_predictions)
    print('Test accuracy: %.4f%%' % test_accuracy)
```

Test accuracy: 36.6029%

## **Predict Dog Breed with the Model**

```
In [105]: from extract_bottleneck_features import *

def VGG16_predict_breed(img_path):
    # extract bottleneck features
    bottleneck_feature = extract_VGG16(path_to_tensor(img_path))
    # obtain predicted vector
    predicted_vector = VGG16_model.predict(bottleneck_feature)
    # return dog breed that is predicted by the model
    return dog_names[np.argmax(predicted_vector)]
```

# Step 5: Create a CNN to Classify Dog Breeds (using Transfer Learning)

You will now use transfer learning to create a CNN that can identify dog breed from images. Your CNN must attain at least 60% accuracy on the test set.

In Step 4, we used transfer learning to create a CNN using VGG-16 bottleneck features. In this section, you must use the bottleneck features from a different pre-trained model. To make things easier for you, we have precomputed the features for all of the networks that are currently available in Keras:

- VGG-19 (https://s3-us-west-1.amazonaws.com/udacity-aind/dog-project/DogVGG19Data.npz)
   bottleneck features
- ResNet-50 (https://s3-us-west-1.amazonaws.com/udacity-aind/dog-project/DogResnet50Data.npz)
   bottleneck features
- Inception (https://s3-us-west-1.amazonaws.com/udacity-aind/dog-project/DogInceptionV3Data.npz)
   bottleneck features
- Xception (https://s3-us-west-1.amazonaws.com/udacity-aind/dog-project/DogXceptionData.npz)
   bottleneck features

The files are encoded as such:

```
Dog{network}Data.npz
```

where {network}, in the above filename, can be one of VGG19, Resnet50, InceptionV3, or Xception. Pick one of the above architectures, download the corresponding bottleneck features, and store the downloaded file in the bottleneck features/ folder in the repository.

# (IMPLEMENTATION) Obtain Bottleneck Features

In the code block below, extract the bottleneck features corresponding to the train, test, and validation sets by running the following:

```
bottleneck_features = np.load('bottleneck_features/Dog{network}Data.npz')
train_{network} = bottleneck_features['train']
valid_{network} = bottleneck_features['valid']
test_{network} = bottleneck_features['test']
```

```
In [22]: ### TODO: Obtain bottleneck features from another pre-trained CNN.
    network = 'Xception'
    checkpointer_path = 'saved_models/weights.best.{0}.hdf5'.format(network)
    feature_path = 'bottleneck_features/Dog{0}Data.npz'.format(network)
    bottleneck_features = np.load(feature_path)
    train_cnn = bottleneck_features['train']
    valid_cnn = bottleneck_features['valid']
    test_cnn = bottleneck_features['test']
```

### (IMPLEMENTATION) Model Architecture

Create a CNN to classify dog breed. At the end of your code cell block, summarize the layers of your model by executing the line:

<your model's name>.summary()

**Question 5:** Outline the steps you took to get to your final CNN architecture and your reasoning at each step. Describe why you think the architecture is suitable for the current problem.

#### **Answer:**

For this task, the most important step is choose the right model. Because we have a relatively small dataset, and I believe the new data set is similar to the dog images that are currently in the ImageNet, which is used in obtaining the advanced models such as VGG, resNet, Xception and Inception.

#### Choosing the model

I have tried all of the four pre-trained models specified for this project. Results quickly emerged that the VGG-19 model is greatly out performed by Resnet-50, Xception and Inception. VGG-19 model does perform better than the VGG-16 used earlier in the project.

Among Resnet-50, Xception and Inception, with a configuration of 20 epochs, batch size of 20, a global average pooling layer and a fully connected layer, they all perform fast and fairly accurate(80%); However, Xception seems to perform slightly better. So I decided to use Xception.

Theoretically (in terms of CNN development) this makes sense. VGG networks is one of the earliest CNN networks that achieved astounding success. However, VGG networks have a few drawbacks: 1) it is slow; 2) the network architecture weights themselves are quite large (in terms of disk/bandwidth; More importantly the networks suffered from the problem of vanishing gradients, in which gradient signals from the error function decreased exponentially as they backpropogated to earlier layers. As a result, after a certain threshold, as the depth of network increase, the performance degrades.

Resnet tries a different approach. Instead of trying to learn an underlying mapping from x to H(x), learn the difference between the two, or the "residual." Resnet performs very well and it solves the vanishing gradients problem. Because that, a lot more layers can be added to the model and can still continously learn from the data.

Inception model employes multiple configurations in parallel in each step. For example, at each layer, Inception uses a set of transformation layers (one 2 by 2, 3 by 3, 5 by 5) with a pooling layer, then let the model pick the "winner". To solve the enormous computation cost, Inception also uses 1x1 convolutions to perform dimensionality reduction.

Xception is Inception on steroids (extreme inception). It also maps out the spatial correlations for each output channel separately and then use a 1x1 depthwise convolution to capture cross-channel correlation.

"cross-channel correlations and spatial correlations are sufficiently decoupled that it is preferable not to map them jointly."

#### Fine-tuning

Once the model is chosen, I simply stripped out the top layer of the trained model and added a global average pooling layer and a dense layer of 133 neurons.

The test accuracy using this model with only 50 epochs is #####85.7656%######. I think it is not bad.

#### Dog breed identifier web app

After the model is trained and tested, I saved the model in .h5 format which contains the architecture and the weights of the model. Then I used keras.load\_model to load the model into a flask application. Together with gunicorn, I am ablt to run the dog breed identifier online. Please try it out:)

Dog Breed Identifier (https://dog-breed-identifier.herokuapp.com/)

## (IMPLEMENTATION) Load the Model with the Best Validation Loss

### (IMPLEMENTATION) Test the Model

Try out your model on the test dataset of dog images. Ensure that your test accuracy is greater than 60%.

### (IMPLEMENTATION) Predict Dog Breed with the Model

Write a function that takes an image path as input and returns the dog breed (Affenpinscher, Afghan hound, etc) that is predicted by your model.

Similar to the analogous function in Step 5, your function should have three steps:

- 1. Extract the bottleneck features corresponding to the chosen CNN model.
- 2. Supply the bottleneck features as input to the model to return the predicted vector. Note that the argmax of this prediction vector gives the index of the predicted dog breed.
- 3. Use the dog\_names array defined in Step 0 of this notebook to return the corresponding breed.

The functions to extract the bottleneck features can be found in extract\_bottleneck\_features.py, and they have been imported in an earlier code cell. To obtain the bottleneck features corresponding to your chosen CNN architecture, you need to use the function

```
extract_{network}
```

where {network}, in the above filename, should be one of VGG19, Resnet50, InceptionV3, or Xception.

```
In [31]: ### TODO: Write a function that takes a path to an image as input
### and returns the dog breed that is predicted by the model.
from extract_bottleneck_features import *

def Xception_predict_breed(img_path):
    # extract bottleneck features
    bottleneck_feature = extract_Xception(path_to_tensor(img_path))
    # obtain predicted vector
    predicted_vector = cnn_model.predict(bottleneck_feature)
    # return dog breed that is predicted by the model
    return dog_names[np.argmax(predicted_vector)]
```

# Step 6: Write your Algorithm

Write an algorithm that accepts a file path to an image and first determines whether the image contains a human, dog, or neither. Then,

- if a **dog** is detected in the image, return the predicted breed.
- if a **human** is detected in the image, return the resembling dog breed.
- if **neither** is detected in the image, provide output that indicates an error.

You are welcome to write your own functions for detecting humans and dogs in images, but feel free to use the face\_detector and dog\_detector functions developed above. You are **required** to use your CNN from Step 5 to predict dog breed.

Some sample output for our algorithm is provided below, but feel free to design your own user experience!

### (IMPLEMENTATION) Write your Algorithm

```
In [32]: ### TODO: Write your algorithm.
    ### Feel free to use as many code cells as needed.

def final_predict(img_path):
    dog_face_detected = 1 if dog_detector(img_path) else 0
    human_face_detected = 1 if face_detector(img_path) else 0
    if dog_face_detected or human_face_detected:
        return 'This looks like {0}, it must be a {0}'.format(Xception_p redict_breed(img_path))
    else:
        return 'Hmmm, something is wrong. This does not look like anything like a dog or even a human'
```

# **Step 7: Test Your Algorithm**

In this section, you will take your new algorithm for a spin! What kind of dog does the algorithm think that **you** look like? If you have a dog, does it predict your dog's breed accurately? If you have a cat, does it mistakenly think that your cat is a dog?

### (IMPLEMENTATION) Test Your Algorithm on Sample Images!

Test your algorithm at least six images on your computer. Feel free to use any images you like. Use at least two human and two dog images.

**Question 6:** Is the output better than you expected:)? Or worse:(? Provide at least three possible points of improvement for your algorithm.

#### **Answer:**

The output is better than I expected, though I am a little disappointed that I am not able to improve it further. No matter how I tried, I could not achieve a better test accuracy score of higher than 85%

Three possible points of improvement for my algorithm could be:

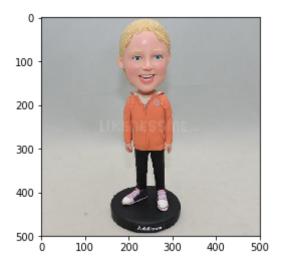

- 1) Dropout layer to reduce overfitting, though when I added a dropout layer, the test accuracy did not improve;
- 2) Obtain more training images;
- 3) Augument the training images by applying scaling, distortion, etc.

```
In [33]: from os import listdir
    import matplotlib.image as mpimg

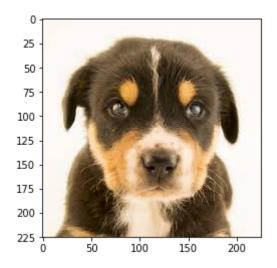

imgdir = 'my-images'

for img in listdir(imgdir):
    img_path= imgdir + '/' + img
    img=mpimg.imread(img_path)
    imgplot = plt.imshow(img)
    plt.show()
    print(final_predict(img_path))

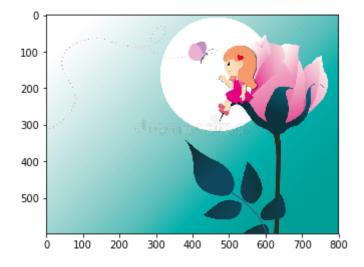

## TODO: Execute your algorithm from Step 6 on
## at least 6 images on your computer.
## Feel free to use as many code cells as needed.
```

This looks like Kuvasz, it must be a Kuvasz

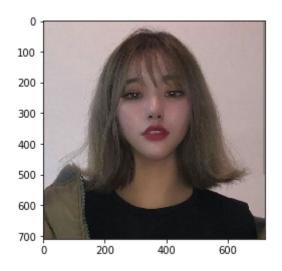

This looks like Greater\_swiss\_mountain\_dog, it must be a Greater\_swiss\_mountain\_dog

Hmmm, something is wrong. This does not look like anything like a dog o r even a human

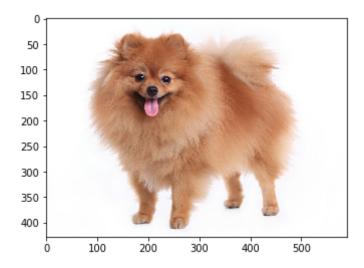

This looks like Bichon\_frise, it must be a Bichon\_frise

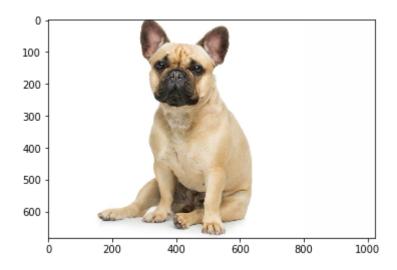

This looks like Dachshund, it must be a Dachshund

This looks like Golden\_retriever, it must be a Golden\_retriever

This looks like Pomeranian, it must be a Pomeranian

This looks like French\_bulldog, it must be a French\_bulldog
